

Exp_DecoupledDots_005m — Accuracy by factor (n = 2051, 4 sessions)

$$\text{log-odds(correct)} = \beta_0 + \beta_1 \cdot F_1 + \beta_2 \cdot F_2 + \beta_3 \cdot F_3 + \beta_7 \cdot F_7 + \beta_{12} \cdot (F_1 \times F_2) + \beta_{17} \cdot (F_1 \times F_7) + \beta_{27} \cdot (F_2 \times F_7)$$

A — Cueing factors

B — Delayed-field properties

Each $F_n \in \{0, 1\}$ (binary predictor). $F_1=1$: cued · $F_2=1$: depth kept · $F_3=1$: color kept · $F_7=1$: trans Near (Far=0). F_4 – F_6 , F_8 – F_9 shown for reference; not in GLM. F_3 entered additively only (no interaction terms).

A — Cueing factors

B — Delayed-field properties C — Translating-field properties

Same data — log-odds scale (what the GLM models)

In GLM (F1, F2, F3, F7) Reference only (F4–F6, F8–F9)

† F9 translating-field rotation = pre-translation rotational identity of that field (during the translation window, dots translate — they do not rotate)
