

BothFar_005m — Session 260411_1225 (both planes behind fixation)

BothFar_005m — Session Notes (GS, 2026-04-11)

Design:

Both depth fields placed behind fixation: Less-Far = +0.05m, More-Far = +0.10m (both uncrossed disparity). Swaps: N / C / Z / CZ. linkDepthColor = 0. Same structure as DecoupledDots_005m except no field crosses the fixation plane.

Jerky motion artifact:

Again observed on a subset of trials — perceived as predominantly upward, occasionally downward or oblique. This is not new; it has been present in prior sessions (DecoupledDots, DepthColorLinked). Trace figures were partly motivated to investigate this. Tentative read: the percept is a rotation-burst artifact (rotational motion briefly dominates the direction report), not a stimulus rendering error per se. No evidence it is specific to BothFar. Warrants further investigation but is likely an observer-side perceptual effect rather than a new stimulus artifact.

Depth separation during swaps:

On some portions of some trials, the red and green dot fields did not appear well-separated in depth. This was most noticeable during or just after depth swaps (Z and CZ conditions). Consistent with a transient vergence disruption at tStart when depth planes reassign — the visual system may need a brief period to re-establish correct vergence to the new plane positions. This is particularly relevant for Z/CZ interpretation: some of the deficit may reflect not just loss of depth-identity continuity, but also a transient period of reduced depth salience.

Direction uncertainty:

Many trials perceived as showing motion but with uncertain exact direction (8AFC, chance = 12.5%). Observer reports frustration with fine direction discrimination. This is expected and consistent with prior sessions — the task is inherently noisy at threshold-level stimulation. Not specific to BothFar.

Key question for this session:

Does the Less-Far/More-Far asymmetry mirror the old Near/Far asymmetry? If the fixation-plane hypothesis is correct, both planes are now beyond the fixation anchor, so the structural bias should be absent or reversed (favouring Less-Far, the plane closer to fixation). If the asymmetry persists in the same direction (More-Far > Less-Far), that would suggest it is not primarily a fixation-plane effect but rather a vergence-comfort effect tied to absolute depth (esophoria account).
